

Mayon Volcano's (13.2500°N, 123.6833°E) seismic network did not record any volcanic earthquake during the past 24-hour observation period. Moderate emission of white steam plumes drifting east-northeast was observed. Crater glow was not observed last night due to thick clouds that covered the volcano's summit. Sulfur dioxide (SO₂) emission on 01 June 2013 was measured at an average of 131 tonnes/day. Ground deformation survey (precise leveling) on the third week of May 2013 showed slight inflation of the edifice compared to February 2012, with the volcano still slightly inflated compared to January 2010 baselines.

Mayon Volcano's alert status remains at **Alert Level 1**, which means that it is at abnormal condition. Although this means that presently no magmatic eruption is imminent, it is strongly advised that the public refrain from entering the 6-kilometer radius Permanent Danger Zone (PDZ) due to the perennial life-threatening dangers of rockfalls, landslides/avalanches at the middle to upper slope, sudden ash puffs and steam-driven or phreatic eruptions from the summit. Active stream/river channels and those identified as perennially lahar-prone areas on all sectors of the volcano should also be avoided especially during extreme weather conditions when there is heavy and prolonged rainfall. DOST-PHIVOLCS maintains its close monitoring of Mayon Volcano and any new development will be communicated to all concerned stakeholders.
